

tradeforme — Next Steps

Action list of things only **you** can do. Everything below is blocked on your input, your credentials, or your decision — not on more code.

Where the project stands

Repository	https://github.com/EtixP/tradeforme (private)
Branch	main
Milestones done	M1 (skeleton), M2 (DART ingestion), M4 (event study + cost model), M5 (strategy engine)
Tests passing	68 / 68
Disclosures in DB	111,622 across 60 trading days (Feb 27 – May 27, 2026)
Supply-contract events	533 “new contract” candidates (title-filtered)
Price data source	pykrx (free, no auth)
LLM extraction	Code complete (prompts + validator + client) — waiting on your API key to actually run
Broker integration	PaperBroker (historical fills) ready; KIS broker needs your credentials

Naive event study, gross and net of costs

533 title-filtered supply-contract disclosures, returns measured from event-day close to T+1/T+2/T+5 close.
Cost model: 0.015%/side broker commission + 10% VAT, 0.18% sale tax, 5bps slippage → **0.313% roundtrip drag**.

Horizon	n	Gross mean	Net mean	Gross win%	Net win%	Profit factor
1-day	533	+0.66%	+0.35%	45.6%	42.8%	1.17
2-day	533	+0.88%	+0.57%	44.5%	43.3%	1.19
5-day	533	+1.28%	+0.96%	44.8%	44.1%	1.22

Honest read: after costs the naive filter is barely above breakeven. Profit factor 1.17 means **1.17 won per 1.00 lost** — mathematically positive but well within noise on 533 events. Win rate is < 50% across all horizons. Median return is negative gross (a few large winners drag the mean up). **This is the expected result.** Per CLAUDE.md, the real test is filtering to contracts where *contract_value / prior_year_revenue* ≥ 8%, which requires LLM extraction (M3). The infrastructure is now ready to drop a key in.

Raw per-event CSV: data/event_study_results.csv

Action items

Sorted by priority. P1 unblocks the next milestone. P2 hardens the existing system. P3 is optional polish.

Priority	What	Why	How
P1	Rotate the DART API key	The current key briefly appeared in open source during the 2022 Smack Attack (see the exploit)	Replace with new key
P1	Get an LLM API key (Anthropic or OpenAI) complete (prompts + validation criteria abstraction)	API keys, key platform and the ML model	Get key from platform
P1	Decide M3 vs more backfill first	M3 needs the LLM key above; tokens are cheap (~\$0.006/60k tokens) and is a good fit for the job	See Milestone 3
P2	Set up GitHub branch protection	Once live trading code exists, you don't want to lose it	Set up branch protection in GitHub
P2	Back up data/kdtb.db	111k rows of ingested DART data	Easy: rent a 10GB drive, backup to it, delete old data
P2	Schedule daily DART ingestion	Right now ingestion only runs when you have the CLI installed	Use cron or systemd to run the CLI
P2	Obtain KIS broker credentials	Required for Milestone 6 (broker integration)	Get credentials from KIS
P2	Review risk thresholds in config	Default defaults match CLAUDE.md	Review config/default.yaml
P3	Install gitleaks pre-commit hook	Catches an accidental commit of .env	Install gitleaks and gitleaks pre-commit hook
P3	Decide if PDF action lists should be included	Currently NFX_STEPS.pdf will be included	Decide if NFX_STEPS should be included
P3	Decide on Korean market holidays	Right now the ingestion CLI runs every day	Optional: add a holiday calendar (e.g. for a holiday)

Where to find things

Project root	/Users/jsp2022310/Desktop/tradeforme
Repo on GitHub	https://github.com/EtixP/tradeforme
Project spec	CLAUDE.md (in repo root)
Source code	src/kdtb/ — schemas, config, data, strategy, risk, storage
Tests	tests/ — run with: <code>.venv/bin/pytest</code>
DART ingestion CLI	<code>scripts/ingest_disclosures.py --date YYYY-MM-DD</code>
Event study CLI	<code>scripts/run_event_study.py [--limit N]</code>
Local DB (gitignored)	<code>data/kdtb.db</code> — SQLite, inspect with <code>sqlite3</code> or DB Browser
Event study CSV	<code>data/event_study_results.csv</code>
Secrets (gitignored)	<code>.env</code> — <code>DART_API_KEY</code> lives here
Config	<code>config/default.yaml</code> , <code>config/paper.yaml</code> , <code>config/live_tiny.yaml</code>
Live-trading guard	<code>src/kdtb/config.py</code> — raises if YAML says LIVE without <code>ENABLE_LIVE_TRADING=true</code> in

How to verify the project is healthy

Run these from the repo root any time you want to confirm nothing is broken:

```
.venv/bin/pytest
```

```
.venv/bin/python -m kdtb.main
```

```
.venv/bin/python scripts/ingest_disclosures.py --date $(date +%Y-%m-%d)
```

What Claude built across the autonomous loops

Loop 1 (M4 + M5):

- **data/market_data_client.py** — pykrx wrapper for OHLCV + event-time returns
- **scripts/run_event_study.py** — batched event study CLI
- **strategy/major_supply_contract.py** — M5 strategy engine (was placeholder)

Loop 2 (cost model + M3 prep + paper broker):

- **backtest/cost_model.py** — Korean equity costs (commission, VAT, sale tax, slippage)
- **backtest/metrics.py** — per-trade metrics (win rate, profit factor, sharpe-ish, max drawdown)
- **interpretation/llm_prompts.py** — versioned extraction prompt template
- **interpretation/extraction_validator.py** — LLM JSON → Extraction with hard/soft validation
- **interpretation/llm_client.py** — Anthropic + OpenAI + Stub clients (no calls until key added)
- **broker/base.py** + **broker/paper_broker.py** — abstract Broker + HistoricalPaperBroker
- 4 new test files (25 new test cases)

Suite: 28 → 43 → 68 passing tests. Zero regressions across both loops.

Honest caveats

- The naive event study uses title-only filtering. It does not separate small contracts from large ones, so noise dominates. M3 (LLM extraction) is needed to filter by contract/revenue ratio.
- The event date used is the DART receipt date (YYYYMMDD). Intraday timing of the disclosure is not captured. If a disclosure is filed at 14:00 KST, our 'T+1' return actually includes the price reaction from 14:00 to next-day close, not a clean next-day-only return.
- Returns are raw close-to-close, not benchmark-adjusted. A market-wide rally on event days would inflate the mean.
- pykrx scrapes the KRX website. It's free but can be rate-limited. We sleep 0.15s between calls.
- LIVE_TINY broker code is not yet implemented. Even with KIS credentials, no real orders can be placed yet.
